WHAT IS CLAIMED IS:

- A method of monitoring a power distribution system, said method comprising increasing a sampling rate for sampling analog monitoring signals from monitoring of said power distribution system until said sampling rate is high enough to capture high-speed transients
- The method of claim 1, further comprising monitoring both current and voltage parameters within lines of said power distribution system to generate said analog monitoring signals.
 - The method of claim 1, further comprising: storing sampled data from said monitoring signals in a memory unit; and analyzing said stored data with a processor.
- The method of claim 3, further comprising displaying sampled data, including detected high-speed transients, or data derived from said sampled data on a monitor.
- The method of claim 3, further comprising interrupting a flow of power on said power distribution system if analysis of said stored data indicates a danger according to pre-defined parameters.
- The method of claim 1, wherein said increasing said sampling rate further comprises increasing said sampling rate in response to user input from a user input device.
- The method of claim 1, wherein said increasing said sampling rate further comprises automatically increasing said sampling rate as part of a monitoring routine for said power distribution system.
